

EPOS4

A MC tool for high-energy scatterings

- Released few weeks ago
<https://klaus.pages.in2p3.fr/epos4/>
thanks Laurent Aphecetche for explaining gitlab pages, nextjs etc
thanks Damien Vintache for managing installation/technical issues
- a full general purpose approach, public, and testable**
- tested (by myself) for 4 GeV - 13000 GeV,
pp to PbPb, light / heavy flavor, collective / hard**
- Papers coming soon**

Parallel vs sequential scattering (primary interactions)

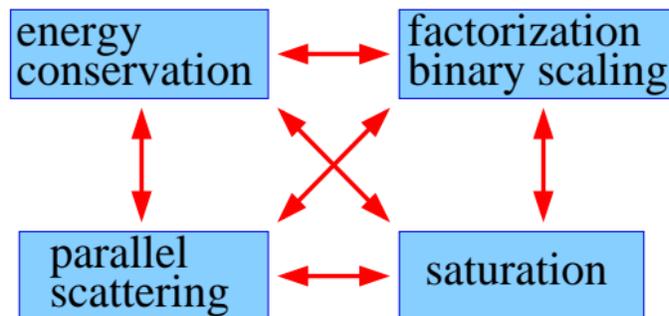

Points
(besides FXT):
Epos
comparisons
to data

**From very elementary time scale arguments:
parallel scheme needed everywhere beyond 25 AGeV,
partly beyond 4 AGeV**

The EPOS4 concept

- implement parallel scattering using appropriate theoretical tools (S-matrix theory)

The S-matrix approach leaves some freedom, but also provides severe constraints which allow to see a deep connection between four crucial concepts

In EPOS<4, we could never accommodate all of them

Factorization / binary scaling is not “assumed”, it must come out!

EPOS S-matrix approach

Parallel "Pomerons" structure of T for pp ($T = T_{ii}$, elastic *) :

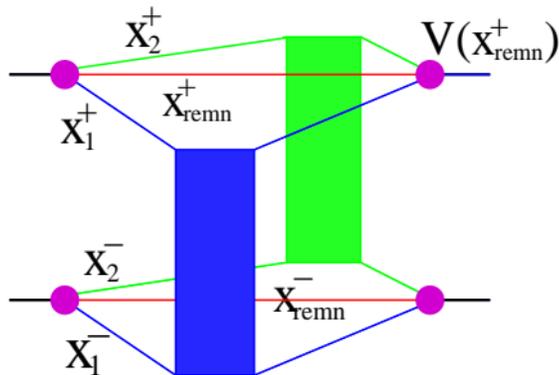

$$iT = \int_{\text{momenta}} \sum_k \frac{1}{k!} V \times \{iT_{\text{Pom}} \times \dots \times iT_{\text{Pom}}\} \times V$$

with V representing connection to projectile / target remnant

Energy-momentum conservation
 x_i^\pm light-cone momentum fractions

$$x_{\text{remn}}^\pm = 1 - \sum x_i^\pm$$

the boxes contain ... whatever
 in our case: parton ladders, i.e.
 all the pQCD part

$$x_{\text{PE},i} = x_i^+ x_i^- \approx S_{\text{Pom},i} / S_{\text{tot}}$$

*) Relation S-matrix - T-matrix: $S_{fi} = \delta_{fi} + i(2\pi)^4 \delta(p_f - p_i) T_{fi}$; $T = T_{ii}$

Generalisation for pA and AA: trivial *)

Just a product of pp expressions:

$$iT = \int_{\text{momenta}} \prod_{i=1}^A V \prod_{n=1}^{AB} \left\{ \sum_k \frac{1}{k!} \{iT_{\text{Pom}} \times \dots \times iT_{\text{Pom}}\} \right\} \prod_{j=1}^B V$$

which does NOT mean at all superposition of pp collisions!

Completely parallel!

No collision sequence!

*) conceptually trivial ... but we have 10 000 000 dimensional non-separable integrals

Connection with inelastic scattering (“optical theorem”)

$$2s \sigma_{\text{tot}} = \frac{1}{i} \text{disc } T = \text{“cut diagram”}$$

so we need to compute the “cut” of the complete diagram, i.e. for pp:

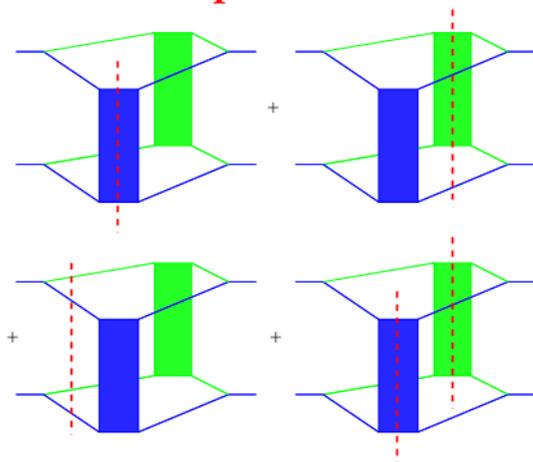

$$\frac{1}{i} \text{disc} \{ V \times iT_{\text{Pom}} \times \dots \times iT_{\text{Pom}} \times V \}$$

and a “cut” multi-Pomeron diagram = sum of all possible cuts

gives a sum of positive and negative terms (which we sum up)

-> interference,
cancellations!

Absolutely crucial!!!

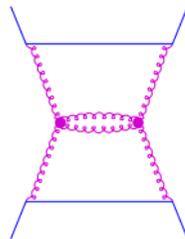

Simple example

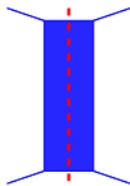

Uncut diagram:

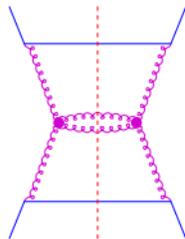

=

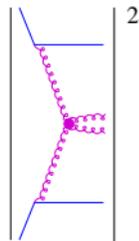

Cut diagram:

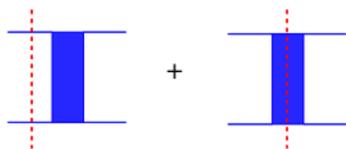

=

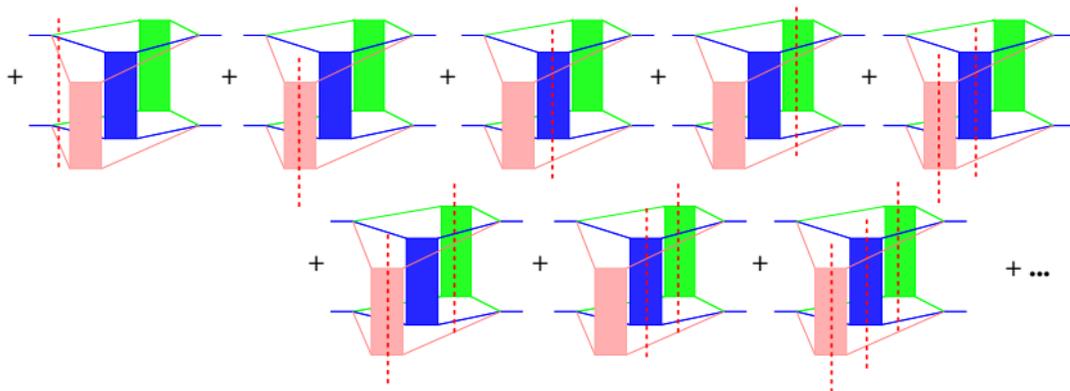

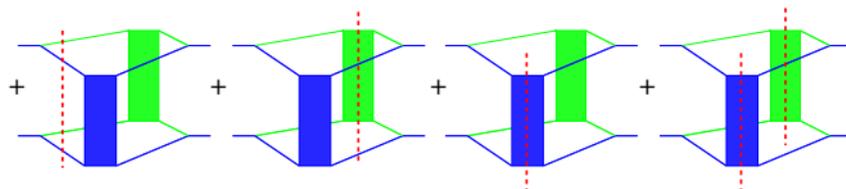

corresponds to:

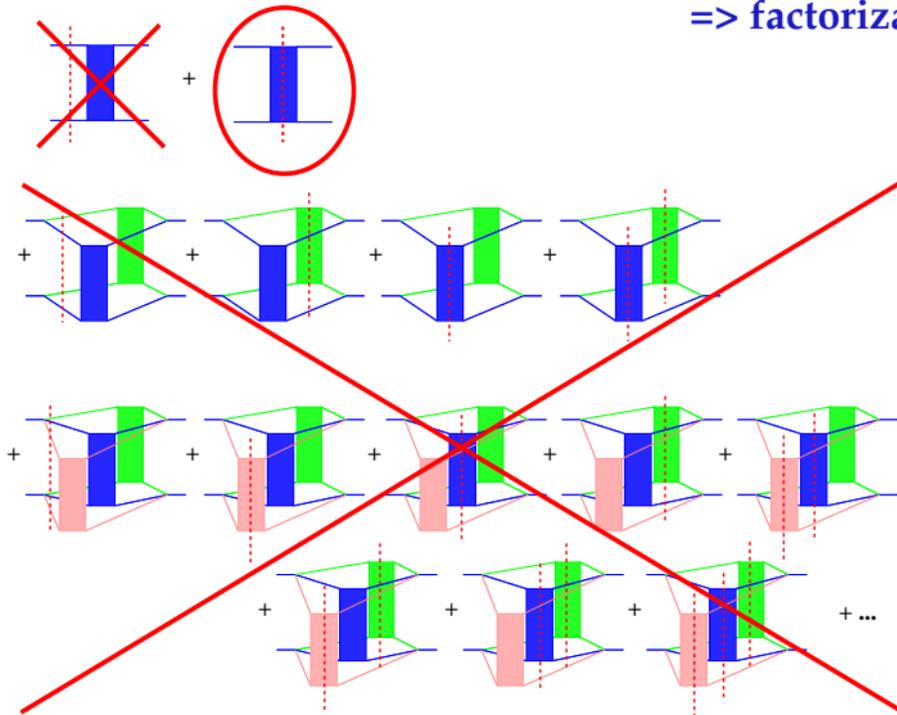

**All the diagrams
which contribute to pp**

For inclusive cross sections, when ignoring energy conservation
everything cancels - up to one diagram

=> factorization

Ignoring energy conservation (remove vertices) one can prove (rigorously) for pp scattering for x^\pm (and so also for pt spectra)

$$\frac{d\sigma_{\text{incl}}^{pp}}{dx^+ dx^-} = \frac{d\sigma_{\text{incl}}^{\text{single Pom}}}{dx^+ dx^-}$$

which means factorization (treating the cancellations is trivial)

and for AB scattering:

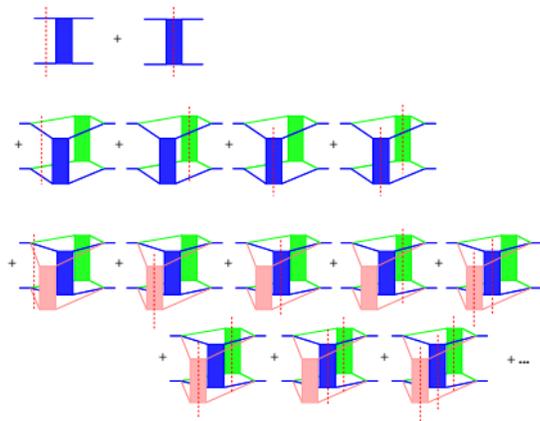

$$\frac{d\sigma_{\text{incl}}^{AB}}{dx^+ dx^-} = AB \frac{d\sigma_{\text{incl}}^{\text{single Pom}}}{dx^+ dx^-}$$

which means binary scaling

Great ... but getting factorization /binary scaling ALWAYS (large and small pt) is not so great ...

so we better keep energy conservation, but here the “cancellation issues” become complicated

The difficulty is

- to keep all diagrams
- make sure that they cancel where they should do so:**
for inclusive cross sections, for “hard probes”
- make sure that energy conservation does not spoil factorization in that case**
(like in EPOS LHC)

To achieve this

- precision concerning the pQCD calculations**
- good strategy to implement saturation**
to cure the factorization issues spoiled by energy conservation

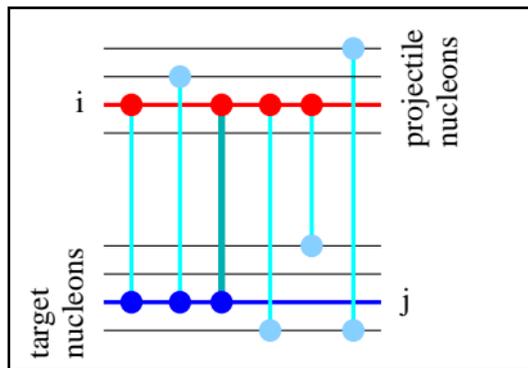

For a given Pomeron, connecting
projectile nucleon i and
target nucleon j

define:

$$N_{\text{conn}} = \frac{N_P + N_T}{2}$$

N_P = number of Pomerons connected to i

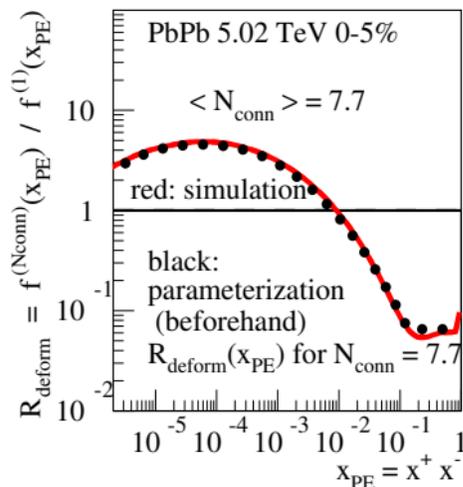

N_T = number of Pomerons connected to j

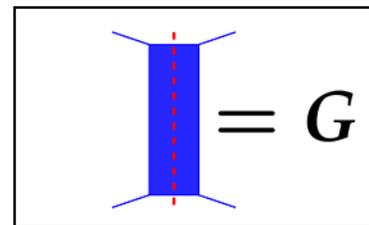

The x_{PE} (Pomeron energy squared)
distribution for $N_{\text{conn}} > 1$ will be
"deformed" wrt the case $N_{\text{conn}} = 1$

$$R_{\text{deform}} = f^{(N_{\text{conn}})} / f^{(1)} \neq 1$$

But we are able to parameterize the
"deformation" beforehand(!)
(iterative process, converges fast)
for all systems, all centrality classes

Now we can define the “box”, called “cut Pomeron” and named $G(x^+, x^-, s, b)$ the crucial building block used in the multi-Pomeron expressions (pp,AA)

For each cut Pomeron, for given x^\pm , s , and b , and for a given functional dependence $G_{\text{QCD}}(Q^2, x^+, x^-, s, b)$ with $G_{\text{QCD}} = \text{DGLAP parton ladder}$, with Q^2 being the low virtuality cutoff

we postulate:

$$G(x^+, x^-, s, b) = \frac{1}{R_{\text{deform}}(x_{\text{PE}})} \times f \times G_{\text{QCD}}(Q_{\text{sat}}^2, x^+, x^-, s, b)$$

with Q_{sat}^2 depending on x^+ , x^- and N_{conn}
 (f is a normalization depending linearly on N_{conn})

which assures factorization and binary scaling, always !

For large N_{conn} , low pt is suppressed, the Pomeron gets “hard”.

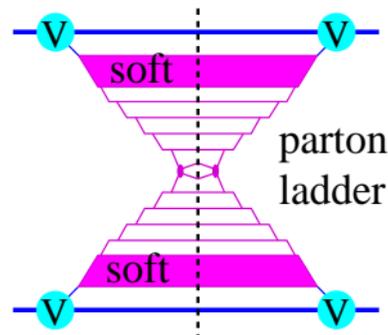

EPOS4 factorization mode (1 Pom) and EPOS4 PDFs

Based on cut single Pomeron diagrams
(composed of soft parts + parton ladder),

we may compute (and tabulate) PDFs,
corresponding to half of the diagram

including Pomeron-nucleon coupling,
excluding the Born process

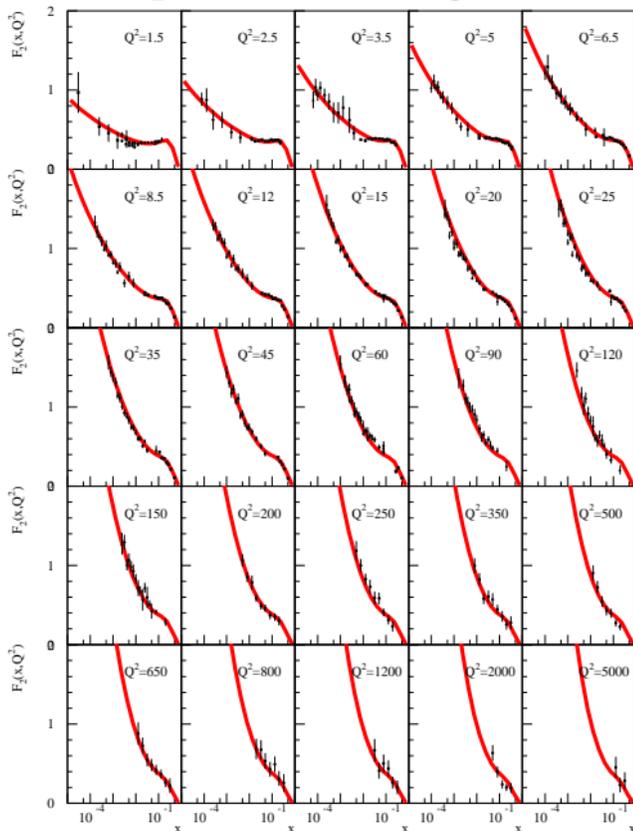

and then express the di-jet cross sections in
terms of the PDFs

$$E_3 E_4 \frac{d^6 \sigma_{\text{dijet}}}{d^3 p_3 d^3 p_4} = \sum_{kl} \int \int dx_1 dx_2 f_{\text{PDF}}^k(x_1, \mu_F^2) f_{\text{PDF}}^l(x_2, \mu_F^2)$$

$$\frac{1}{32s\pi^2} \sum |\mathcal{M}^{kl \rightarrow mn}|^2 \delta^4(p_1 + p_2 - p_3 - p_4)$$

Electron-proton scattering F_2 vs x

To check our f_{PDF} , we can compute

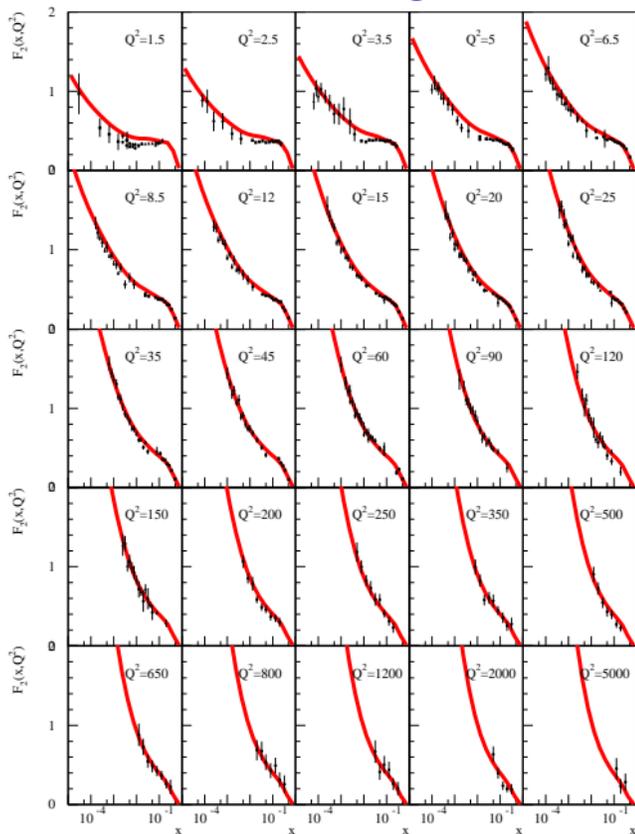

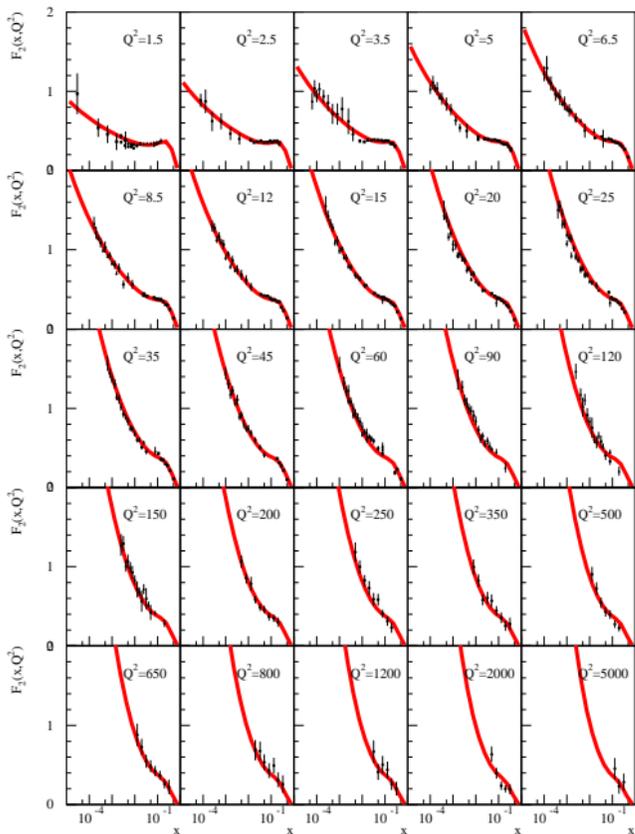

$$F_2 = \sum_k e_k^2 x f_{\text{PDF}}^k(x, Q^2)$$

with

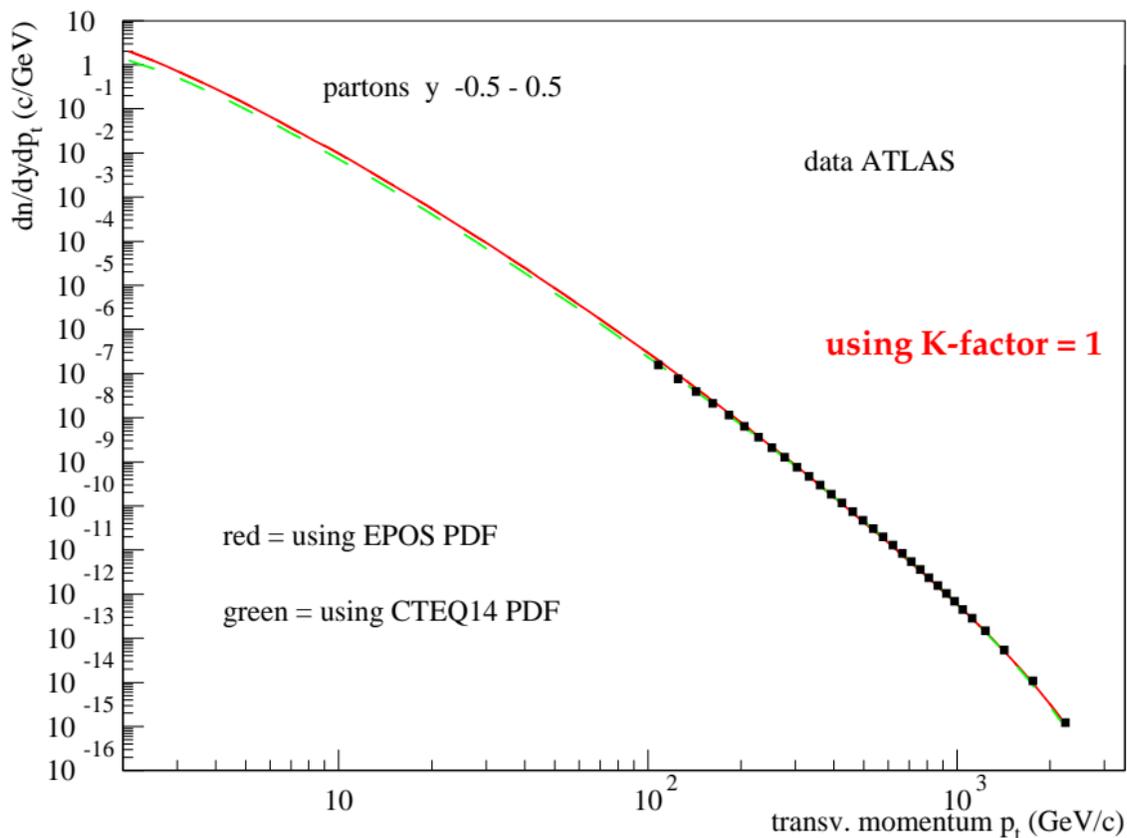

$$x = x_B = \frac{Q^2}{2pq}$$

in the EPOS framework, and compare with data from ZEUS, H1

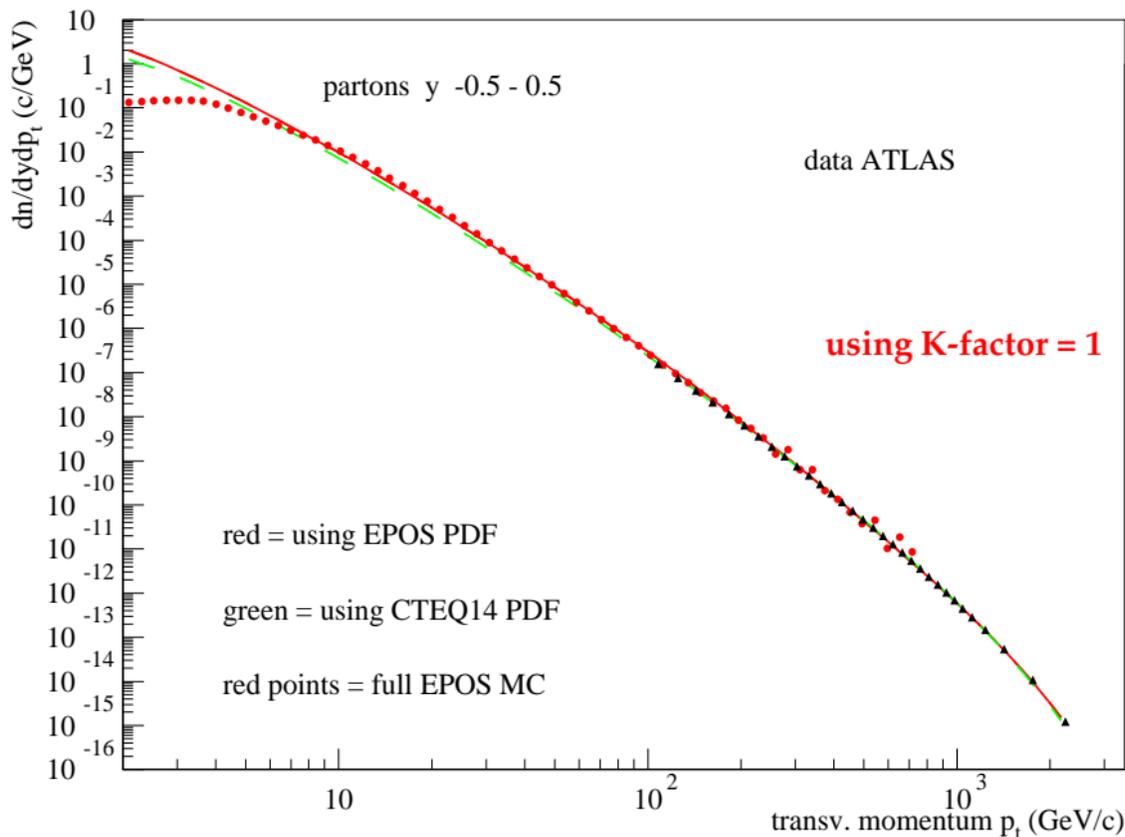

F_2 with EPOS PDF (left) and CTEQ14(5f) PDF (right)

Jet cross section vs pt for pp at 13 TeV

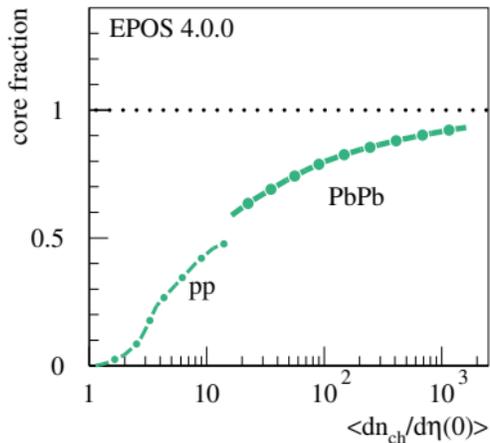

Jet cross section vs pt for pp at 13 TeV

Full EPOS4, core + corona, hydro, microcanonical decay: checking multiplicity dependencies

Core fraction

Core: microcanonical
NEW FO concept
NEW numerical methods
used for pp and AA

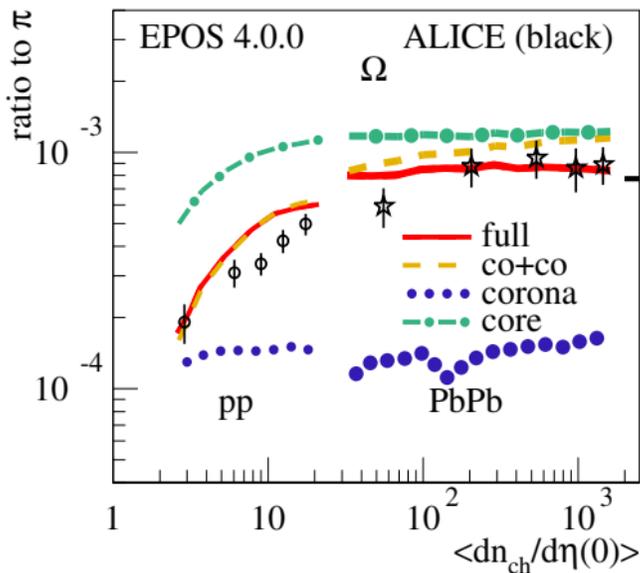

Microcanonical core alone does not work!

Check
 in the following

- hadron to pion ratios
- mean pt

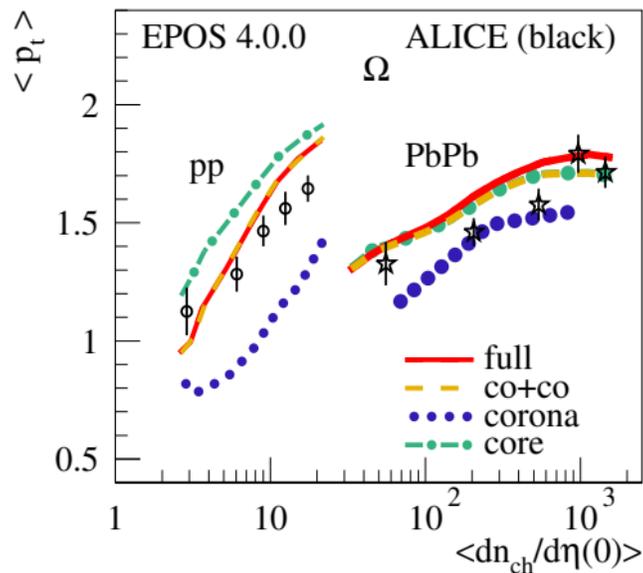

versus multiplicity
in core-corona approach

continuous curve

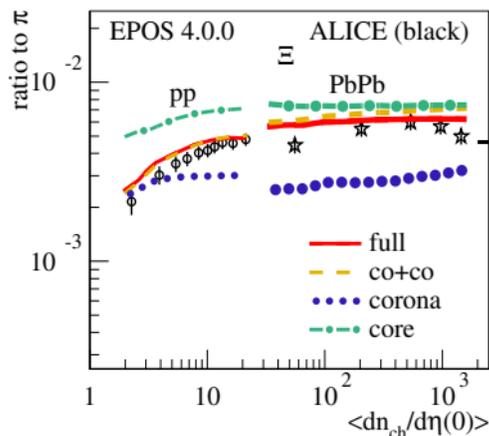

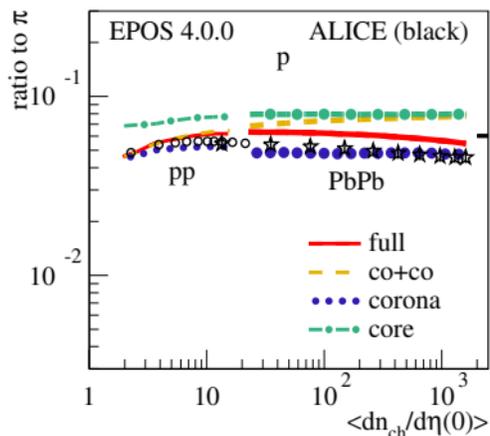

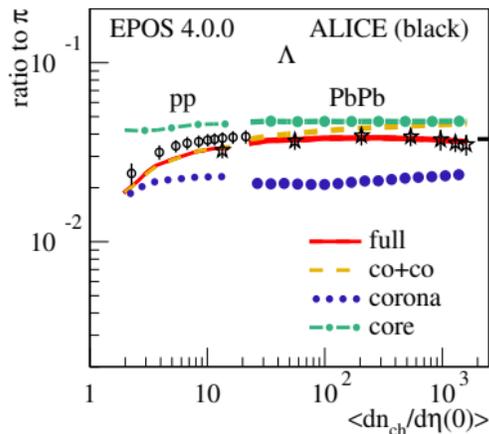

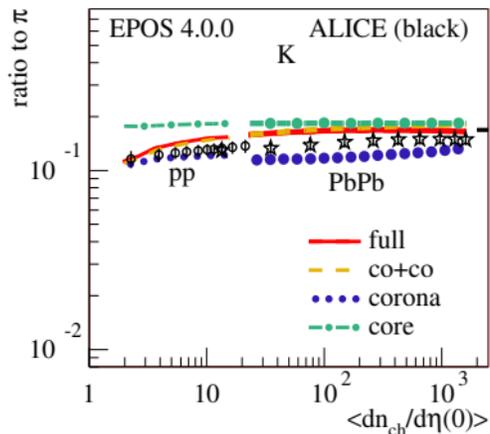

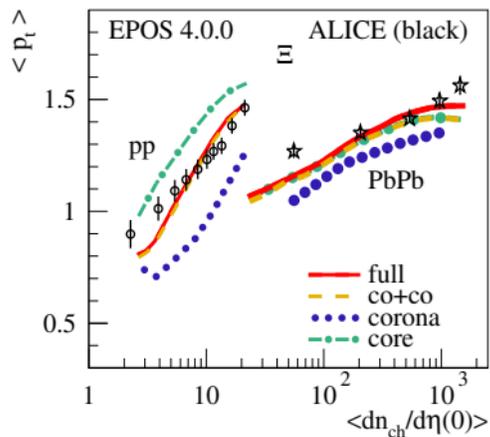

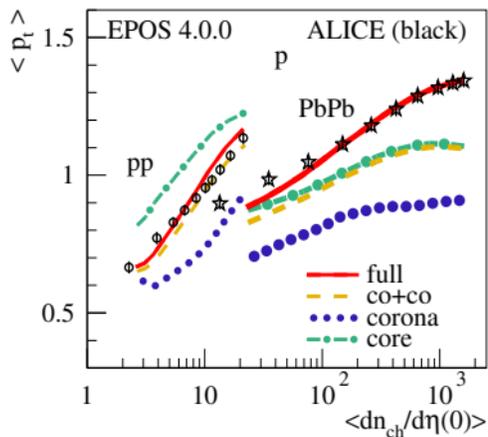

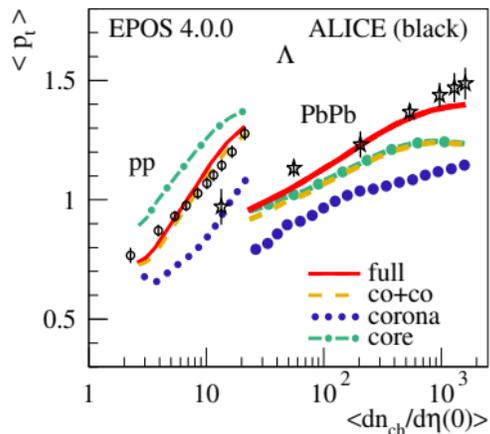

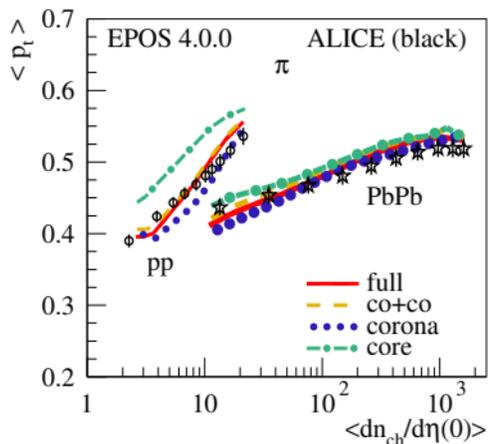

core-corona effect
+ microcanonical effect

jump

core-corona effect
saturation effect
+ flow effect

Crucial in all cases

- core-corona**
- saturation**
- flow**
- mirocanonical**

all of them !!!

Multiplicity dependence of charm production

saturation and flow effect

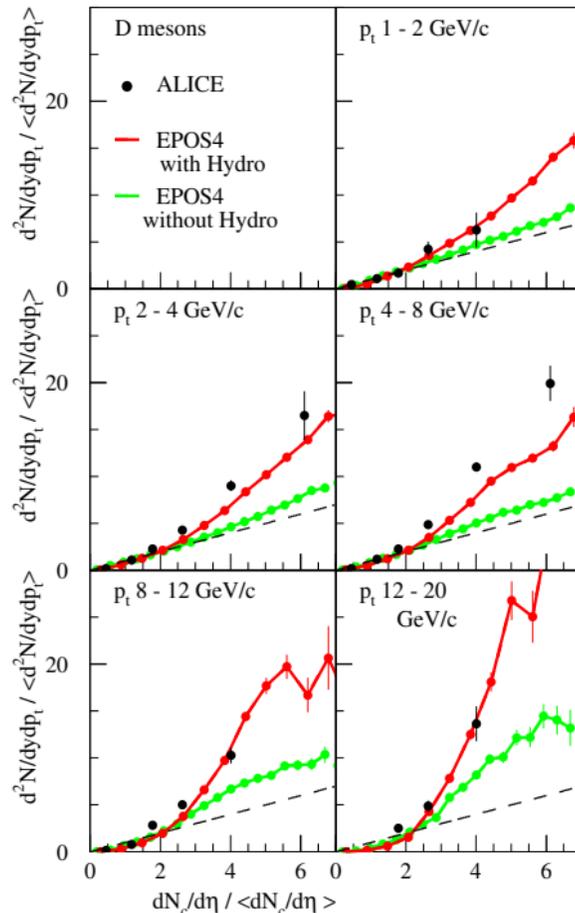

pp 7TeV

Self-normalized D meson
multiplicity

for different transverse
momentum ranges

versus self-normalized charged
particle multiplicity,

compared to ALICE data

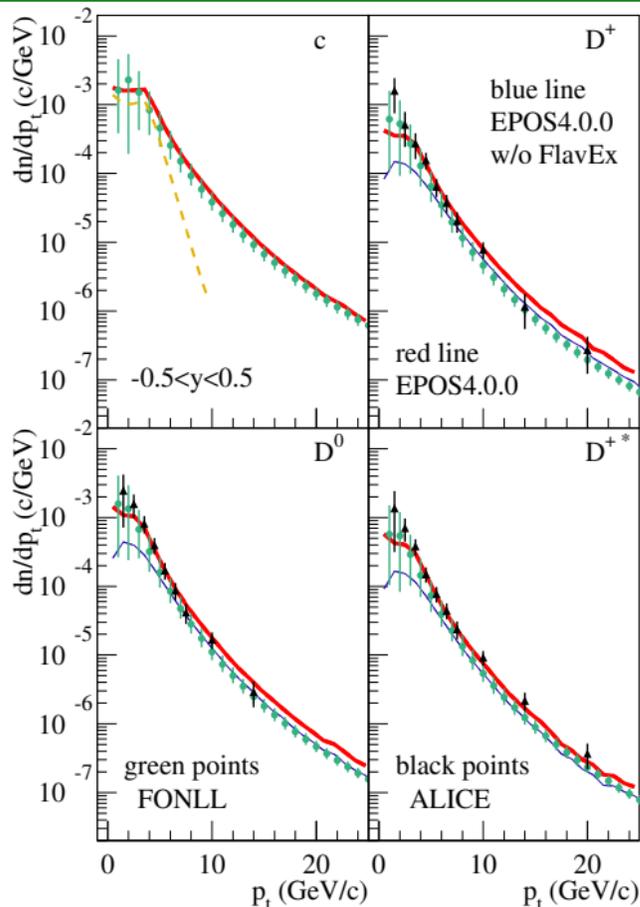

Charmed hadrons

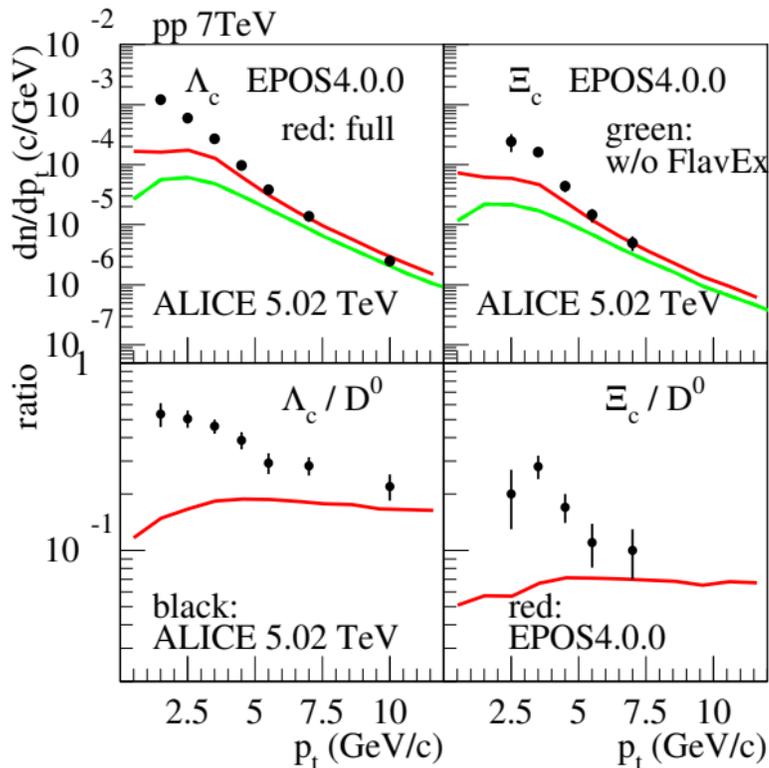

pp 7TeV

charmed final partons
and mesons

EPOS4 simulations
w/o hydro,

compared to ALICE data
and FONLL

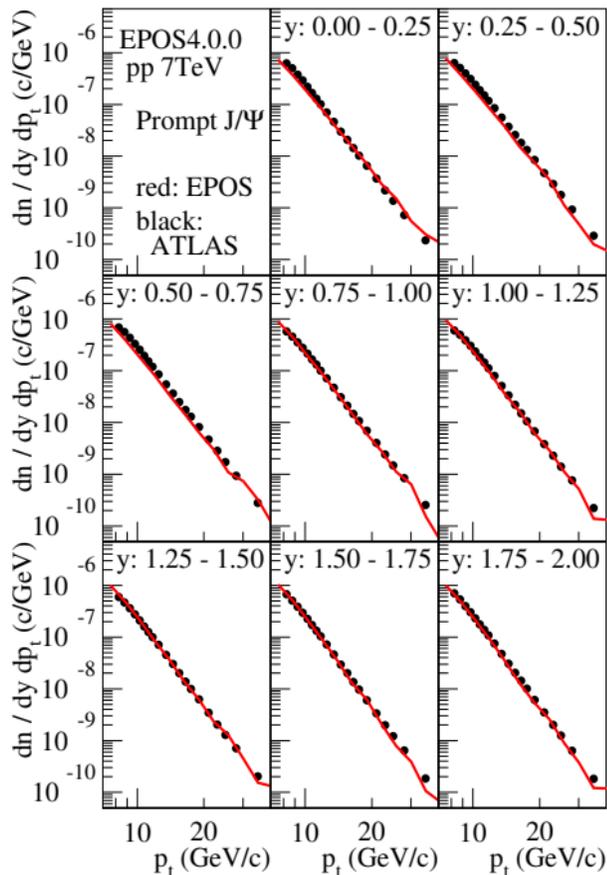

pp 7TeV
 charmed baryons

Λ_c and Ξ_c

EPOS4 simulations
 w/o hydro,

compared to ALICE data
 (at 5.02 TeV).

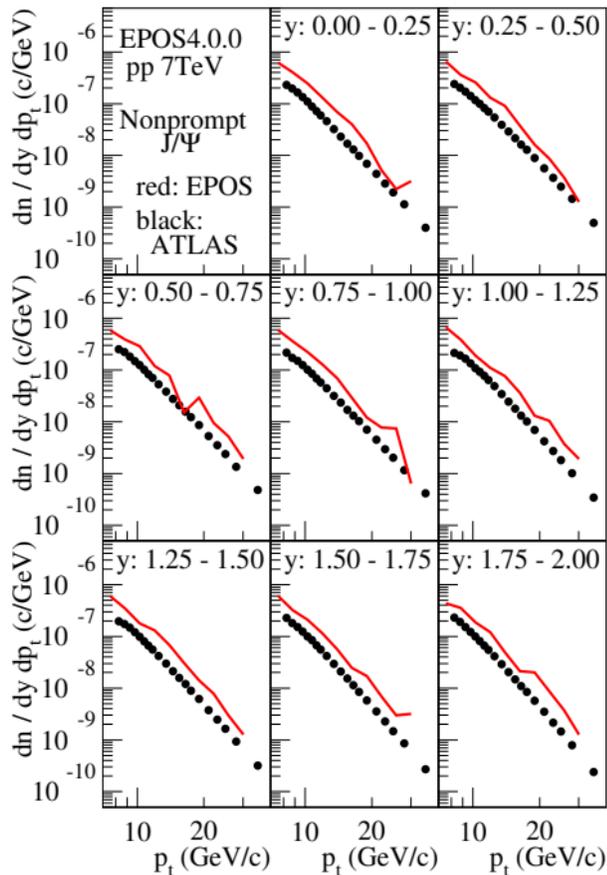

Deficit at low p_t ...
 thermal?

pp 7TeV
Prompt J/Ψ

compared to ATLAS

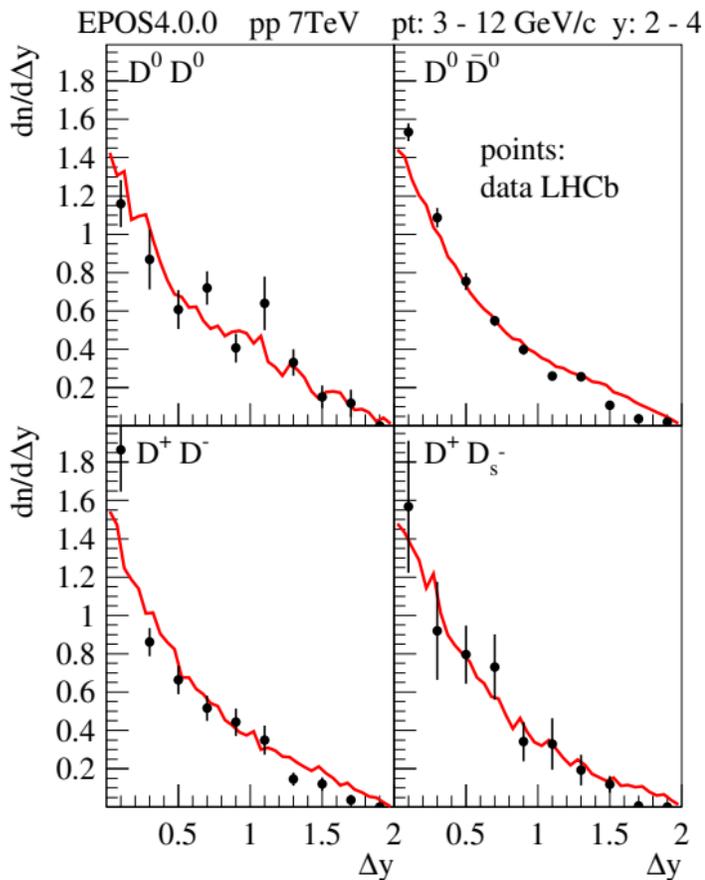

EPOS J/Ψ production:
Color Evaporation Model

pp 7TeV
Nonprompt J/Ψ

compared to ATLAS

strange: B spectra are very good

pp 7TeV Two hadron correlations

$$D^0 D^0$$

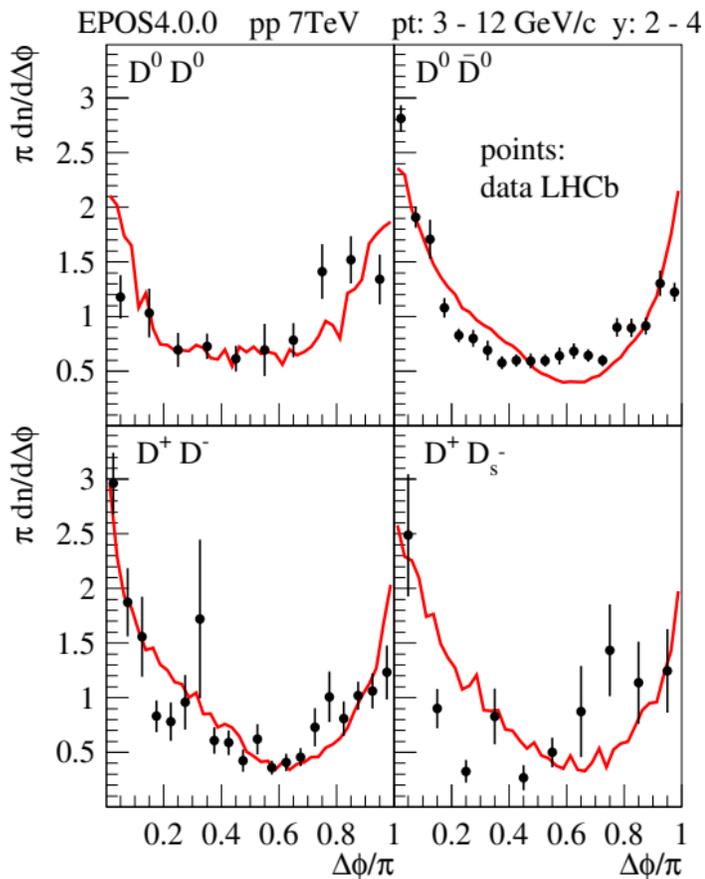

$$D^0 \bar{D}^0$$

$$D^+ D^-$$

$$D^+ D_s^-$$

as a function of Δy

compared to LHCb

pp 7TeV Two hadron correlations

$$D^0 D^0$$

$$D^0 \bar{D}^0$$

$$D^+ D^-$$

$$D^+ D_s^-$$

as a function of $\Delta\phi$

compared to LHCb

Summarizing the EPOS4 project

accomodate simultaneously

Energy conservation + **P**arallel scattering + fact **O**rization + **S**aturation

representing **4** crucial concepts of HE scattering
