Overview

- ▶ Introduction
- ▶ A first example
- ▶ Kinematic space
- ▶ Generic flow equations
- ▶ What does $K_m^n K_n^m - K^2 = 0$ mean?
- ▶ Summary

Introduction

Introduction

- ▶ One important approach to complexity is *path integral optimization*

[Caputa et al. 2017a] [Caputa et al. 2017b].

- ▶ Further progress came in [Boruch et al. 2021b]:

- ▶ Idea: Compute action between boundary cutoff and bulk surface Q , *extremise* w.r.t. scale factor of metric of Q .
- ▶ Add tension term T to action on $Q \rightarrow$ plays role of emergent time.
- ▶ This provides *finite cutoff corrections* to Liouville approach beyond $\partial\phi \ll e^\phi$.
- ▶ Further work in [Boruch et al. 2021a] [Caputa et al. 2022] [Camargo et al. 2022].
- ▶ Around the same time, we were considering a similar setup, leading up to [Chandra et al. 2021].

Basic idea

- ▶ Consider a subregion M of Euclidean Poincaré AdS_3 .
- ▶ Introduce two time-slices $t = t_{i/f}$ corresponding to the ground states $|0\rangle_{z_{i/f}}$ at different values of the radial cutoff.
- ▶ The radial boundary is at finite cutoff, $z = \rho(t)$.
- ▶ **Proposal:** Complexity of the circuit that maps between $|0\rangle_{z_{i/f}}$ is given by the gravitational action on M .

A first example

Simple example - setup

We consider Euclidean AdS, with the curvature scale $l_{AdS} = 1$:

$$ds^2 = \frac{dz^2 + dt^2 + dx^2}{z^2}. \quad (1)$$

Bulk action:

$$I = \frac{1}{\kappa} \int_M d^3x \sqrt{G} (\mathcal{R} + 2) + \frac{2}{\kappa} \int_{\partial M} d^2x \sqrt{g} K + I_c. \quad (2)$$

- ▶ M is the bulk region bounded by $\rho(t) \leq z \leq \infty$ and $t_i \leq t \leq t_f$
- ▶ Bulk term
- ▶ Surface terms
- ▶ Joint terms $I_c = \frac{2}{\kappa} \int dx \sqrt{j} \alpha$ [Hartle and Sorkin]₁₉₈₁ [Hayward]₁₉₉₃

Simple example - boundary surface

We investigate the bulk region M
bounded by $\rho(t) \leq z \leq \infty$ and $t_i \leq t \leq t_f$.

The induced line element on the boundary surface is

$$ds^2 = \frac{(1 + \dot{\rho}^2)dt^2 + dx^2}{\rho^2}, \quad (3)$$

hence

$$R = \frac{2(\rho\ddot{\rho} - \dot{\rho}^2(1 + \dot{\rho}^2))}{(1 + \dot{\rho}^2)^2}, \quad (4)$$

$$K = \frac{\rho\ddot{\rho} + 2(1 + \dot{\rho}^2)}{(1 + \dot{\rho}^2)^{3/2}}. \quad (5)$$

Simple example - action

We obtain

$$\begin{aligned} I &= \frac{-4}{\kappa} \int_M d^2x \int_{z=\rho}^{\infty} \frac{dz}{z^3} + \frac{2}{\kappa} \int_{\partial M} d^2x \frac{\rho\ddot{\rho} + 2(1 + \dot{\rho}^2)}{\rho^2(1 + \dot{\rho}^2)} + I_c[\rho] \\ &= \frac{2V_x}{\kappa} \int_{t_i}^{t_f} dt \frac{\rho\ddot{\rho} + (1 + \dot{\rho}^2)}{\rho^2(1 + \dot{\rho}^2)} + I_c[\rho] \end{aligned} \quad (6)$$

for the on-shell bulk action ($V_x = \int dx$). For the corner term, we also find

$$I_c = \frac{2V_x}{\kappa} \left(\frac{\pi/2 - \arctan \dot{\rho}(t_f)}{z_f} + \frac{\pi/2 + \arctan \dot{\rho}(t_i)}{z_i} \right). \quad (7)$$

Integrating by parts, this action can be written only using first derivatives of ρ , yielding

$$I = \frac{2V_x}{\kappa} \int_{t_i}^{t_f} dt \left(\frac{1}{\rho^2} + \frac{\dot{\rho} \arctan \dot{\rho}}{\rho^2} \right) + \frac{\pi V_x}{\kappa} \left(\frac{1}{z_f} + \frac{1}{z_i} \right). \quad (8)$$

Simple example - action

We obtain

$$\begin{aligned} I &= \frac{-4}{\kappa} \int_M d^2x \int_{z=\rho}^{\infty} \frac{dz}{z^3} + \frac{2}{\kappa} \int_{\partial M} d^2x \frac{\rho\ddot{\rho} + 2(1 + \dot{\rho}^2)}{\rho^2(1 + \dot{\rho}^2)} + I_c[\rho] \\ &= \frac{2V_x}{\kappa} \int_{t_i}^{t_f} dt \frac{\rho\ddot{\rho} + (1 + \dot{\rho}^2)}{\rho^2(1 + \dot{\rho}^2)} + I_c[\rho] \end{aligned} \quad (6)$$

for the on-shell bulk action ($V_x = \int dx$). For the corner term, we also find

$$I_c = \frac{2V_x}{\kappa} \left(\frac{\pi/2 - \arctan \dot{\rho}(t_f)}{z_f} + \frac{\pi/2 + \arctan \dot{\rho}(t_i)}{z_i} \right). \quad (7)$$

Integrating by parts, this action can be written only using first derivatives of ρ , yielding

$$I = \frac{2V_x}{\kappa} \int_{t_i}^{t_f} dt \left(\frac{1}{\rho^2} + \frac{\dot{\rho} \arctan \dot{\rho}}{\rho^2} \right) + \frac{\pi V_x}{\kappa} \left(\frac{1}{z_f} + \frac{1}{z_i} \right). \quad (8)$$

Simple example - eoms

The equations of motion obtained by extremizing (8) read

$$\frac{\rho\ddot{\rho} + (1 + \dot{\rho}^2)}{\rho^3(1 + \dot{\rho}^2)^2} = 0. \quad (9)$$

The generic solution to (30) reads

$$\rho(t) = \sqrt{\mathfrak{R}^2 - (t - t_0)^2} \quad (10)$$

and describes **semi-circular arcs** of radius \mathfrak{R} . The **equal time slice** $\dot{\rho} \rightarrow \infty$ corresponds to the limit of infinite radius.

Simple example - on-shell action

With boundary being $\rho(t_f) = z_f$ and $\rho(t_i) = z_i$, the value of the Euclidean action in the first term of (8) is

$$I = \frac{2V_x}{\kappa} \left(\frac{1}{z_f} \arctan \frac{z_i^2 - z_f^2 + \Delta t^2}{2z_f \Delta t} - \frac{1}{z_i} \arctan \frac{z_i^2 - z_f^2 - \Delta t^2}{2z_i \Delta t} \right). \quad (11)$$

Now extremising w.r.t. Δt (keeping $z_i \neq z_f$ fixed) gives $\Delta t = 0$, i.e. $\Re \rightarrow \infty$, and

$$I_{min} = \frac{c\pi V_x}{24} \left(\frac{1}{z_f} - \frac{1}{z_i} \right). \quad (12)$$

→ We recover the complexity=volume proposal?!

Simple example - comparison to Liouville

For $\dot{\rho} \ll 1$,

$$I = \frac{2V_x}{\kappa} \int_{t_i}^{t_f} dt \left(\frac{1}{\rho^2} + \frac{\dot{\rho} \arctan \dot{\rho}}{\rho^2} \right) \approx \frac{2V_x}{\kappa} \int dt \left(\frac{1}{\rho^2} + \frac{\dot{\rho}^2}{\rho^2} \right), \quad (13)$$

which, assuming no x -dependence, is equivalent to the Liouville Lagrangian

$$S_L = \frac{c}{24\pi} \int dt \int dx \left(\eta e^{2\omega} + (\partial_t \omega)^2 + (\partial_x \omega)^2 \right). \quad (14)$$

after a change of variables $\rho(t) \rightarrow (1/\sqrt{\eta}) e^{-\omega(t)}$. The equations of motion derived from (13) take the form

$$\frac{\rho \ddot{\rho} + (1 - \dot{\rho}^2)}{\rho^3} = 0. \quad (15)$$

Comparison to Boruch et al.

Note that [Boruch et al. 2021b] investigates a setup similar to us, and up to notation (6) also appears in the appendix of that paper. Following [Boruch et al. 2021b], we introduce a conformal time u , with

$$du = \sqrt{1 + \dot{\rho}(t)^2} dt, \quad (16)$$

such that the line element (3) is transformed into the conformal gauge form

$$ds^2 = \frac{du^2 + dx^2}{\varrho(u)^2}. \quad (17)$$

with the new $\varrho(u(t)) = \rho(t)$. The action now reads [Boruch et al. 2021b]

$$I = \frac{2V_x}{\kappa} \int_{u_i[\varrho]}^{u_f[\varrho]} du \left(\frac{\sqrt{1 - \varrho'^2} + \varrho' \arcsin \varrho'}{\varrho^2} \right). \quad (18)$$

Comparison to Boruch et al.

From this, [Boruch et al. 2021b] obtains eoms

$$\frac{\varrho \varrho'' + 2(1 - \varrho'^2)}{\varrho^3(1 - \varrho'^2)^2} = 0, \quad (19)$$

which are *inequivalent* to our eoms, which in terms of ϱ and u take the **Liouville form**:

$$\frac{\varrho \varrho'' + (1 - \varrho'^2)}{\varrho^3} = 0. \quad (20)$$

Problem: Integral $\int_{u_i[\varrho]}^{u_f[\varrho]} du$ has ρ -dependent boundary conditions!

→ [Boruch et al. 2021b] and [Chandra et al. 2021] study *different variational problems!*

Kinematic space

Kinematic space approach

Let us analyse the same problem from a **kinematic space** [Czech et al. 2015] point of view:

At each point
($z = \rho(t), t, 0$), there is a
geodesic (with endpoints
at $(t_1(t), t_2(t))$) tangent
to the cutoff surface. We
find:

$$t_{1,2}(t) = \quad (21)$$

$$t + \rho\dot{\rho} \pm \rho\sqrt{\dot{\rho}^2 + 1}.$$

Kinematic space approach

Kinematic space (for $x = \text{const.}$ slice):

$$ds_{ks}^2 = \frac{-dt_1 dt_2}{(t_1 - t_2)^2}. \quad (22)$$

Consider now the action

$$S_{ks} \sim \int \frac{dx}{\rho} ds_{ks}(t), \quad (23)$$

with the coordinate x in units of the cutoff ρ . This results in

$$S_{ks} \sim \int dt dx \left| \frac{\rho \ddot{\rho} + (1 + \dot{\rho}^2)}{\rho^2 (1 + \dot{\rho}^2)} \right|, \quad (24)$$

which agrees with the bulk action in the form (6) as long as $\rho \ddot{\rho} \geq -(1 + \dot{\rho}^2)$ (path in kinematic space is [timelike!](#)).

For the solutions of (30), (24) vanishes identically!

Generic flow equations

Generic Flow Equations

We use the ADM formalism [Arnowitt et al. 1962] to write the metric as

$$ds^2 = N^2 dr^2 + g_{mn}(x, r)(dx^m + N^m dr)(dx^n + N^n dr) \quad (25)$$

and the Lagrangian in terms of canonical variables

$$\mathcal{L} = \sqrt{g} (\pi^{mn} \partial_r g_{mn} - NH - N^m H_m), \quad (26)$$

$$\pi_{mn} = -(K_{mn} - Kg_{mn}) \quad (27)$$

where the lapse and shift functions appear as Lagrange multipliers enforcing

$$H = H^m = 0. \quad (28)$$

Generic Flow Equations

To describe the flow we imagine starting with a surface at constant r and moving the cutoff slightly so that $r \rightarrow r + \epsilon(x)$. Then

$$\delta_\epsilon S = 2 \int \sqrt{g} \epsilon(x) (K^{mn} K_{mn} - K^2), \quad (29)$$

We hence obtain the *flow equations*

$$K_m^n K_n^m - K^2 = 0. \quad (30)$$

What does $K_m^n K_n^m - K^2 = 0$ mean?

Equation of Motion

Our considerations in [Chandra et al.]₂₀₂₁ [Chandra et al.]₂₀₂₃ led us to study co-dimension one surfaces Q embedded into AdS according to the equation

$$K_m^n K_n^m - K^2 = 0. \quad (30)$$

Notation [Poisson]₂₀₀₄:

- ▶ m, n, \dots : indices for surface coordinates y^m ; μ, ν, \dots : indices for ambient space coordinates x^μ .
- ▶ $e_a^\alpha = \partial x^\alpha / \partial y^a$: projectors to surface tangent space; n^α : normal vector
- ▶ g_{mn} : induced metric; $G_{\mu\nu}$: bulk metric.
- ▶ K_{mn} : extrinsic curvature tensor of the surface; $K = K_n^n$.
- ▶ \mathcal{R} : ambient space (bulk) curvature; R : induced curvature etc.

Equation of Motion

Our considerations in [Chandra et al.]₂₀₂₁ [Chandra et al.]₂₀₂₃ led us to study co-dimension one surfaces Q embedded into AdS according to the equation

$$K_m^n K_n^m - K^2 = 0. \quad (30)$$

Brute force ansatz:

- ▶ Define embedding $z = f(t, x)$.
- ▶ Calculate $K_{ij}[f, f', f'', \dot{f}, \dots]$.
- ▶ Solve (30) as nonlinear PDE for f
- ▶ **Problem is only tractable in particularly simple/symmetric setups.**

See [Chandra et al.]₂₀₂₁.

Equation of Motion

Our considerations in [Chandra et al.]₂₀₂₁ [Chandra et al.]₂₀₂₃ led us to study co-dimension one surfaces Q embedded into AdS according to the equation

$$K_m^n K_n^m - K^2 = 0. \quad (30)$$

Motivation 1:

- ▶ Is there a more elegant approach?
- ▶ E.g., (30) is matrix equation for K_m^n .
- ▶ Given a solution K_m^n , can we find corresponding embedding?
- ▶ Similar approach in [Fonda et al.]₂₀₁₇ to holo. EE. in higher curvature theories.

Equation of Motion

Our considerations in [Chandra et al.]₂₀₂₁ [Chandra et al.]₂₀₂₃ led us to study co-dimension one surfaces Q embedded into AdS according to the equation

$$K_m^n K_n^m - K^2 = 0. \tag{30}$$

Motivation 2:

In vacuum, due to the [Hamiltonian constraint](#)

$$0 \equiv H = R - 2\Lambda - (K_m^n K_n^m - K^2), \tag{31}$$

equation (30) demands that the Ricci curvature R of the induced metric of the surface is constant. Specifically, for $d = 3$ and AdS-radius $\Lambda = -1$, then $\mathcal{R} = -6$ and $R = -2 \rightarrow$ looking for *constant curvature surfaces*.

Darboux's observation

As pointed out in [Barbot et al.₂₀₁₁], the French mathematician Darboux once remarked that:

It can be said that the total curvature has more importance in Geometry; as it depends only on the line element, it comes into play in all questions concerning the deformation of surfaces. In mathematical physics, on the contrary, it is the mean curvature [i.e. extrinsic curvature] which seems to play the dominant role [Darboux₁₈₈₉].

Jean-Gaston Darboux
1842 – 1917

Darboux's observation

More than 130 years later, Darboux's observation still seems to hold true, at least in AdS/CFT!

- ▶ The Ryu-Takayanagi formula

[^{Ryu and Takayanagi}₂₀₀₆] demonstrates the role of surfaces with *constant (vanishing) extrinsic curvature* in the holographic dictionary.

- ▶ "*Darboux's question*" in AdS/CFT:

Do surfaces of *constant intrinsic curvature* have a role in AdS/CFT, and if yes, which one?

Jean-Gaston Darboux

1842 – 1917

Solving the equations of motion

Equations of motion:

$$K_m^n K_n^m - K^2 = 0 \quad (30)$$

$$\Leftrightarrow$$

$$R = 2\Lambda \text{ (in vacuum)} \quad (32)$$

$$\Leftrightarrow$$

$$\det K_{mn} = 0 \text{ (in } d_{induced} = 2) \quad (33)$$

Ansatz:

$$K_{mn} \equiv m_m m_n k \quad (34)$$

(generic in $d_{induced} = 2$, subset of solutions in $d_{induced} > 2$)

Solving the equations of motion

Codazzi equations ^[Poisson]₂₀₀₄:

$$\mathcal{R}_{\alpha\beta\gamma\delta} e_a^\alpha e_b^\beta e_c^\gamma e_d^\delta = R_{abcd} \pm (K_{ad}K_{bc} - K_{ac}K_{bd}) \quad (35)$$

$$\mathcal{R}_{\mu\beta\gamma\delta} n^\mu e_b^\beta e_c^\gamma e_d^\delta = K_{bc|d} - K_{bd|c} \quad (36)$$

$$\left(\mathcal{R}_{\alpha\beta} - \frac{1}{2} \mathcal{R} G_{\alpha\beta} \right) n^\beta e_a^\alpha = K_{a|b}^b - K_{,a} \quad (37)$$

($\mathcal{R} \sim$ ambient; $R \sim$ induced geometry; $e_a^\alpha \sim$ projectors; $n^\beta \sim$ normal)

Solving the equations of motion

Codazzi equations $\left[\begin{smallmatrix} \text{Poisson} \\ 2004 \end{smallmatrix} \right]$, using ansatz $K_{mn} \equiv m_m m_n k$:

$$\mathcal{R}_{\alpha\beta\gamma\delta} e_a^\alpha e_b^\beta e_c^\gamma e_d^\delta = R_{abcd} \pm (K_{ad}K_{bc} - K_{ac}K_{bd}) \quad (35)$$

$$\Rightarrow \mathcal{R}_{\alpha\beta\gamma\delta} e_a^\alpha e_b^\beta e_c^\gamma e_d^\delta = R_{abcd} \pm 0 \quad (38)$$

($\mathcal{R} \sim$ ambient; $R \sim$ induced geometry; $e_a^\alpha \sim$ projectors; $n^\beta \sim$ normal)

Hence if the ambient space is (locally) maximally symmetric

$$\mathcal{R}_{\alpha\beta\gamma\delta} = \frac{\mathcal{R}}{d(d-1)} (G_{\alpha\gamma}G_{\beta\delta} - G_{\alpha\delta}G_{\beta\gamma}), \quad (39)$$

then so is the induced metric of the surface with $R = \frac{d-2}{d}\mathcal{R}$.

Solving the equations of motion

Furthermore, $G_{\alpha\beta}n^\beta e_a^\alpha = 0$ (ambient space is locally AdS), and (setting $k = \pm 1$, m_n unnormalised) we find:

$$\mathcal{R}_{\mu\beta\gamma\delta}n^\mu e_b^\beta e_c^\gamma e_d^\delta = K_{bc|d} - K_{bd|c} \quad (36)$$

$$\Rightarrow 0 = m_c \nabla_d m_b + m_b \nabla_d m_c - m_d \nabla_c m_b - m_b \nabla_c m_d. \quad (40)$$

Now, set $d = 3$ and introduce $l^\alpha m_a = 0, l^\alpha l_a = \text{const}$. Thus:

$$0 = m_d l^c l^b \nabla_c m_b \Rightarrow 0 = l^c l^b \nabla_c m_b. \quad (41)$$

$$l^b m_b = 0 \Rightarrow 0 = l^c \nabla_c (l^b m_b) = (l^c \nabla_c l^b) m_b + \underbrace{l^c l^b \nabla_c m_b}_{=0}. \quad (42)$$

Also, $(l^c \nabla_c l^b) l_b \propto l^c \nabla_c l^b l_b = 0$ and hence $l^c \nabla_c l^b = 0$ – geodesic equation.

Solving the equations of motion

Recall:

$$l^a m_a = 0 \Rightarrow K_{ab} l^a l^b = 0 \quad (43)$$

The relation between the covariant derivative in the ambient space $X_{;\beta}$ and the covariant derivative in the induced metric $X|_b$ gives [Poisson 2004]

$$l^{\alpha}_{;\beta} e_b^\beta = l^a|_b e_a^\alpha \pm l^a K_{ab} n^\alpha. \quad (44)$$

Contracting (44) with l^b , we find

$$\underbrace{l^\beta l_{;\beta}^\alpha}_{\text{ambient space geodesic eq.}} = \underbrace{l^b l|_b^a}_{\text{induced metric geodesic eq.}} e_a^\alpha \pm l^b l^a K_{ab} n^\alpha. \quad (45)$$

The surface is foliated by curves which are geodesics in the ambient space.

Solving the equations of motion

The surface with $R = -2$ is foliated by curves which are geodesics in the ambient space (with $\mathcal{R} = -6$).

Analogue statement in \mathbb{R}^3 :

All developable surfaces (i.e. $R = 0$) are ruled surfaces (i.e. foliated by straight lines) [Krivoshapko and Ivanov₂₀₁₅], however the converse is not true.

Example 1: Euclidean AdS₃, Poincaré-patch

Background:

$$ds^2 = \frac{1}{z^2} (dt^2 + dx^2 + dz^2) \quad (46)$$

Solution for [strip of varying width](#):

$$z(t, x) = \sqrt{r(t)^2 - x^2}, \quad (47)$$

Generalizes case of constant width studied in [Chandra et al. 2021].

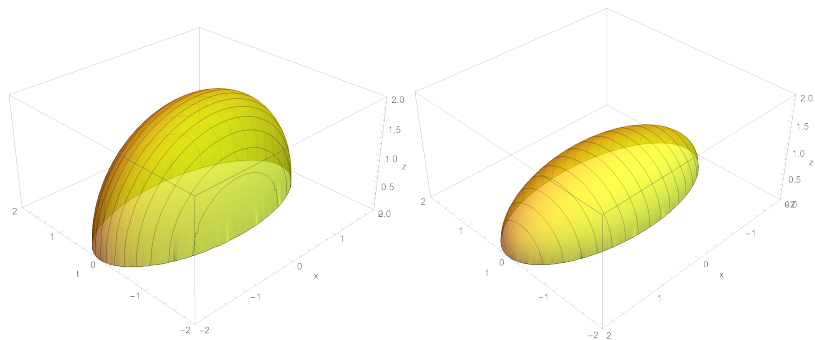

Example 2: Uniqueness?

Background:

$$ds^2 = \frac{1}{z^2} (dt^2 + dx^2 + dz^2) \quad (48)$$

For elliptic boundary region, there are two hypersurfaces satisfying (30) with the same boundary condition at $z = 0$. For one we find $K < 0$ everywhere, while for the other one we find $K > 0$ everywhere.

Example 3: Lorentzian (global) AdS₃, spacelike surfaces

Background:

$$ds^2 = \frac{1}{\cos(\theta)^2} (-dt^2 + d\theta^2 + \sin(\theta)^2 d\phi^2), \quad (49)$$

Solution:

$$t(\phi, \theta) = t_{bdy} \left[\arctan \left(\sqrt{\csc^2(\theta) \sec^2(\phi) - 1} \right) \right] \quad (50)$$

where $t_{bdy}[\phi]$ is the boundary condition at the asymptotic boundary $\theta = \pi/2$ which we assume to be symmetric under $\phi \rightarrow -\phi$.

Example 4: "Lemons"

Let's now search for **timelike surfaces** in Lorentzian AdS.

Timelike oscillating geodesic:

$$t(\theta) = \pm \arctan \left(\frac{E \sin(\theta)}{\sqrt{-1 + E^2 \cos(\theta)^2}} \right), \quad \phi = \text{const.} \quad (51)$$

where the "energy" $E > 1$ of the geodesic is related to its turning point θ_{max} by $\theta_{max} = \arccos 1/E$. we can construct surfaces of the form

$$t(\theta, \phi) = \pm \arctan \left(\frac{E(\phi) \sin(\theta)}{\sqrt{-1 + E(\phi)^2 \cos(\theta)^2}} \right) + \text{const.} \quad (52)$$

where we have promoted E to a ϕ -dependent parameter.

K diverges at $\theta = 0$ where the surfaces will have a **conical singularity**.

From top-left to bottom-right: $E(\phi) = \sqrt{2}$, $E(\phi) = 2 \sin(2\phi) + \cos(4\phi) + 5$, $E(\phi) = 5 \sin^2\left(\frac{\phi}{4}\right) + \sqrt{2}$,
 $E(\phi) = \tan^4\left(\frac{\phi}{2}\right) + \sqrt{2}$, $E \rightarrow \infty$, and
 $E(\phi) = \left(\frac{\cos(\phi)}{\sin(\phi)}\right)^2 + 2$ for $0 < \phi < \pi$, $E(\phi) = -i \left(\left(\frac{\cos(\phi)}{\sin(\phi)}\right)^2 + 2 \right)$ for $\pi < \phi < 2\pi$.

Lemons, Observations:

- ▶ All lemons have "height" $\Delta t = \pi$.
- ▶ Action inside finite Lemons is $I_{EH} + I_{GHY} = 4\pi^2$, independent of E by construction: These surfaces bound regions of the bulk whose action does not change under infinitesimal deformations of their boundary.
- ▶ Imaginary values of $E(\phi)$ lead to spacelike surfaces that reach the boundary.
- ▶ $t(\theta, \phi) = \theta$, for $E \rightarrow \infty$; surface becomes *null boundary of WDW patch*.

Lemons, Questions/Speculations:

- ▶ All lemons have "height" $\Delta t = \pi$.
→ Is there a specific $T\bar{T}$ deformation that describes a theory living on this surface?
- ▶ Action inside finite Lemons is $I_{EH} + I_{GHY} = 4\pi^2$, independent of E .
- ▶ Imaginary values of $E(\phi)$ lead to spacelike surfaces that reach the boundary.
→ Complexify coordinates?
- ▶ $t(\theta, \phi) = \theta$, for $E \rightarrow \infty$; surface becomes null boundary of WdW patch.
→ Value of action in this limit?
→ $E \gg 1$ as regularisation of WdW-patch?
→ WdW patch arises naturally, without "infinite tension" limit of [Boruch et al. 2021a].

Kinematic space connection?

The solutions to the flow equation

$$K_m^n K_n^m - K^2 = 0. \quad (30)$$

are foliated by geodesics of the ambient space.

That means: these surfaces are described by *curves in the space of geodesics* (\sim kinematic space [Czech et al. 2015]), generalised in

[Czech et al. 2016] [Czech et al. 2020] [Chagnet et al. 2022]).

\Rightarrow Can we phrase our results from a kinematic space perspective?

Summary

Summary and outlook

- ▶ Groundwork laid in [Caputa et al.]_{2017a} [Caputa et al.]_{2017b} [Boruch et al.]_{2021b} with *path integral optimization*.
- ▶ In simple **Euclidean** case, extremising action under a dynamic cutoff surface reproduces equal time slice/CV proposal [Chandra et al.]₂₀₂₁.
- ▶ Generalisation to **Lorentzian case** is non-trivial, with many challenges (e.g. boundedness of action) [Chandra et al.]₂₀₂₃.
- ▶ Universal **flow equation** derived in [Chandra et al.]₂₀₂₁ can be solved quite generally → suggests connection to **kinematic space**.

Gauss-Bonnet theorem

Implications of the Gauss-Bonnet theorem

Consider the Gauss-Bonnet theorem ^[Troyanov]₁₉₉₁

$$\int_Q \frac{R}{2} dV + \int_{\partial Q} k_g ds + \sum_{\text{corners } c} \alpha_c + \sum_{\text{conical sing. } s} \beta_s = 2\pi\chi, \quad (53)$$

As we are searching for $2d$ surfaces of constant scalar curvature, we find

$$\int_Q \frac{R}{2} dV = \frac{R}{2} V < 0 \quad (54)$$

So for $\chi \geq 0$ (includes all Lorentzian cases), surface either needs to reach boundary *or* have conical singularities!

Conical singularities in the Gauss-Bonnet formula

In order to derive the contribution of **conical singularities**, we start with

$$\int_Q \frac{R}{2} dV + \int_{\partial Q} k_g ds + \sum_{\text{(old) corners } c} \alpha_c + X_{\text{conical sing.}} = 2\pi\chi. \quad (55)$$

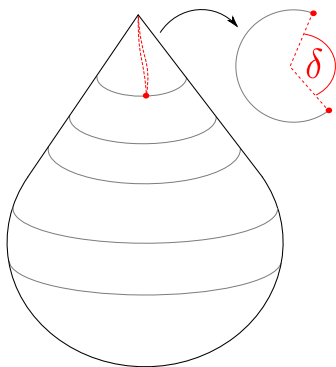

We resolve the singularity by introducing a cut:

$$\int_Q \frac{R}{2} dV + \int_{\partial Q} k_g ds + \sum_{\text{(old) corners } c} \alpha_c + \sum_{\text{new corners } c} \alpha_c = 2\pi(\chi - 1). \quad (56)$$

Comparing (55) and (56), we find

$$X_{\text{conical sing.}} = \sum_{\text{new corners } c} \alpha_c + 2\pi = \alpha_{c1} + \alpha_{c2} + 2\pi = \delta. \quad (57)$$

with $\alpha_{c1} = -\pi$, $\alpha_{c2} = -(\pi - \delta)$, and **deficit angle** δ .

Left: Introducing a cut to derive contribution from conical singularities in Euclidean case.

Right: Lorentzian deficit angle for lemon surface.

Lorentzian case

For the Lorentzian Gauss-Bonnet theorem, see e.g. [Helzer¹⁹⁷⁴]. One has to define the (always real valued) oriented *Lorentzian angle* δ between two future pointing normalised timelike vectors X and Y to satisfy

$$\cosh(\delta) = -X \cdot Y. \quad (58)$$

The Lorentzian Gauss-Bonnet-theorem then takes the form

$$\int_Q \frac{R}{2} dV + \int_{\partial Q} k_g ds + \sum_{\text{corners } c} \alpha_c + \sum_{\text{conical sing. } s} \beta_s = 0, \quad (59)$$

Firstly, the right hand side automatically vanishes ($\chi \equiv 0$), secondly, traversing a closed timelike geodesic polygon in flat space yields the total Lorentzian angle

$$\alpha_{12} + \alpha_{23} + \dots + \alpha_{n1} = 0. \quad (60)$$

Application to Lemons

Assume E indep. of ϕ . Induced metric:

$$ds^2 = \frac{1}{\cos(\theta_2)^2} (-dt_2^2 + d\theta_2^2), \quad (61)$$

with

$$4\text{arctanh}\left(\tan\left(\frac{\theta_{max,2}}{2}\right)\right) = 2\pi \tan(\theta_{max,3}). \quad (62)$$

Hence:

$$\frac{RV}{2} = -4\pi \tan(\theta_{max,3}) = -4\pi \sqrt{E^2 - 1}. \quad (63)$$

Application to Lemons

$$\frac{RV}{2} = -4\pi \tan(\theta_{max,3}) = -4\pi \sqrt{E^2 - 1}. \quad (63)$$

Tangent vectors of boundary geodesics:

$$X_{\pm}^m = \begin{pmatrix} X_{\pm}^{t_2} \\ X_{\pm}^{\theta_2} \end{pmatrix} = \begin{pmatrix} E_2 \\ \pm \sqrt{E_2^2 - 1} \end{pmatrix} \quad (64)$$

Hence:

$$\delta_{\text{future conical sing.}} = \text{arccosh}(-X_+ \cdot X_-) = 2\pi \tan(\theta_{max,3}) \quad (65)$$

$$= \delta_{\text{past conical sing.}} \quad (66)$$

Gaus-Bonnet theorem

$$\frac{RV}{2} + \delta_{\text{past conical sing.}} + \delta_{\text{future conical sing.}} = 0. \quad (67)$$

is satisfied.

Lemons in higher dimensions

"Lemons" in higher dimensions

Let's consider global Lorentzian AdS_4 ,

$$ds^2 = \frac{1}{\cos(\theta)^2} \left(-dt^2 + d\theta^2 + \sin(\theta)^2 d\psi^2 + \sin(\theta)^2 \sin(\psi)^2 d\phi^2 \right), \quad (68)$$

(boundary at $\theta = \pi/2$) and assume rotational symmetry. Ansatz:

$$t(\theta, \psi, \phi) = f(\theta). \quad (69)$$

Equation (30) then yields the ODE

$$4 \cot(\theta) f'(\theta) f''(\theta) - 2 \left(\csc^2(\theta) + 2 \right) f'(\theta)^2 \left(f'(\theta)^2 - 1 \right) = 0, \quad (70)$$

$$\Rightarrow f'(\theta) = \pm \frac{\sqrt{\sin(2\theta)} \cot(\theta)}{\sqrt{C + \sin(2\theta) \cot^2(\theta)}} \quad (71)$$

$$f'(\theta) = + \frac{\sqrt{\sin(2\theta) \cot(\theta)}}{\sqrt{C + \sin(2\theta) \cot^2(\theta)}} \text{ for } C \text{ between } -1 \text{ (blue) and } 1 \text{ (red)}. \text{ AdS}_4$$

boundary is at $\theta = \pi/2$.

- ▶ $C = 0 \Rightarrow f' = 1 \Rightarrow$ null boundary of the WDW patch.
- ▶ $C > 0 \Rightarrow f' \leq 1 \Rightarrow$ spacelike surface reaching to the boundary.
- ▶ $C < 0 \Rightarrow f' \geq 1 \Rightarrow$ Lemon like surface which turns around at finite $\theta_{max} \leq \pi/2$.

$$f'(\theta) = + \frac{\sqrt{\sin(2\theta) \cot(\theta)}}{\sqrt{C + \sin(2\theta) \cot^2(\theta)}} \text{ for } C \text{ between } -1 \text{ (blue) and } 1 \text{ (red)}. \text{ AdS}_4$$

boundary is at $\theta = \pi/2$.

Differences and similarities to $d = 3$:

- ▶ $K_{mn} \neq m_m m_n k$
- ▶ $f'(0) = 1$ for any C , hence induced metric ($\neq \text{AdS}_3$) is degenerate at tip; curvature singularity in Kretschmann scalar.
- ▶ "Height" (time-span) of $\text{AdS}_{d \geq 4}$ lemons depends on C (\sim turning point).
